|----|--|---------------------|--------------------------------|----------------|
| 1 | Comment | Reviewer | Action to be Taken Category | Gasco Priority |
| 2 | First paragraph, last sentence. Final boundary for the GASCO sediment sites will be defined in the Portland Harbor ROD. The text should be revised to note the final boundary will be defined in the Portland Harbor ROD. | CDM/S | Revise | Low |
| 3 | EPA's ability to waive ARARs is limited to specific instances such as the fund lead waiver or the technical impracticability waiver. The circumstances under which ARARs may be waived by EPA should be discussed. | CDM/S | Comment | Medium |
| 4 | Regarding the FEMA floodrise requirement, the EE/CA "interprets the threshold as "less than 0.005 feet," based on the assumption that hydraulic model results less than 0.005 feet would be rounded to 0.00 feet and therefore meet the criterion." This seems inconsistent with the threshold used for the McCormick and Baxter cap project and in any case should be confirmed. | CDM/S | Evaluate | Medium |
| 5 | The EE/CA Report states: All of the alternatives are expected to comply with the five primary ARARs evaluated in detail, with the possible exceptions of certain WQS/NRWQC and FEMA flood regulations. The implications of this statement should be discussed. For example, the placement of capping material may need to be offset through removal of material to allow attainment of the FEMA floodrise requirements. | CDM/S | Evaluate | Medium |
| 6 | NW Natural will need to consider the aggregate impacts of all habor-wide capping activities when evaluating the FEMA flood rise requirement. This section should state this more clearly. | EPA | Revise | Medium |
| 7 | The basis for the statement, "Generally, for upland data evaluations, PCBs and DDx are not reviewed because the Gasco and Siltronic properties have not been identified as sources of these chemicals" should be provided. | Yakama - Ridolfi | Confirm | Low |
| 8 | Paragraph 2, Purpose and Organization Section: The statement is made that U.S Environmental Protection Agency guidance (EPA 540-R-00-002) was followed in developing the cost estimates. In comparing the cost estimates to the EPA guidance document, the opinion of probable costs does not comply with this guidance manual or with any defensible professional estimate structure with backup documentation. There are numerous deficiencies in the presentation and details of Probable Cost Summary. Examples include: no use of element or sub-element details that show units of measure and unit costs; no provision of detailed cost back-up; no presentation to support a management level review; and no discussion of the time expected to achieve remedial action objectives and goals (which affects monitoring level of effort and cost). The estimate should be revised to comply with the EPA guidance document including, at a minimum, presentation of the quantity build-ups; units of measure and unit rates; summaries of the time periods over which the costs occur: back-up and supporting documentation for the costs: and expected times to achieve remediation goals. | CDM/S | Revise | High |
| 9 | Because there is no supporting data on unit rates, derivation of quantities, or presentation of execution details (such as the element and sub-element structures as described in the EPA guidance document for cost estimating) one cannot support the accuracy of the cost estimates nor the validity of the cost comparison between alternatives. The absence of supporting documentation does not allow an independent review and/or verification of relative costs. The reviewer is expected to accept the cost values on faith, not data. Please supply the data and cost back-up to support the evaluation. | CDM/S | Revise | High |
| 10 | The scope of work categories that are shown are too diverse and broad of scope to have been developed by valid parametric methods. For example, a cost is provided for Shoreline Excavation ranging from \$570,000 to about \$2.6 million without describing the nature of the work, productivity, the type of machinery, labor rates, or other relevant | CDM/S | Revise | High |
| 11 | There is no presentation of unit rates (these must be back-calculated from total cost and unit quantities), no indication of whether unit rates are inclusive or exclusive of overhead and profit, no indication of whether these rates are for material only or not, and no sources or back-up for the unit rates, such as vendor or supplier quotes. Please detail the costs that are included in the unit rates. | CDM/S | Revise | High |
| 12 | If, as cited in the text, data from past projects was used, there appears to be no application of adjustment of historical pricing to 2012 values. If past cost data was used, please clarify if costs were corrected to 2012 values. | CDM/S | Revise | Low |
| 13 | If data was used from different projects, there is no indication that any location normalization was applied to the different data sources to obtain a value representative of the | CDM/S | Revise | Low |
| 14 | The capital costs are represented as occurring essentially in year 1 of the project, with no consideration of whether the alternatives require more than a year to implement. If the alternatives extend beyond 1 year, one would traditionally apply time-value-of-money factors and indicate those values in the calculations. Please indicate if the work occurs in the current cost year; if there are capital costs anticipated beyond the first year, please indicate as such and show any cost adjustments inclusive of the time-value-of-money or other corrections. | CDM/S | Revise | Low |
| 15 | There is inconsistency between applied percentages for indirect costs between the text and cost tables. For example, the text states that construction management and daily oversight costs are estimated at 3%, whereas Table 1-3 uses 5%. Similarly, the text states Daily Agency Oversight and Project Management at 5%, while Table 1-3 uses 3%. Please correct as appropriate. | CDM/S | Revise | Medium |
| 13 | There is no presentation of the work elements that make up the long-term maintenance activities with associated costs. There is no indication of the time-value-of-money values used to calculate the net present worth. Please provide this information. The use of percent factors in calculating indirect costs should be reviewed for reasonableness and adjusted accordingly. For example, a construction management cost of about | CDM/S | Revise | High |
| 16 | \$9.8 million is applied to Alternative 5, low cost option. If one assumes a 2 year construction project (note there is no indication by the authors as to the duration), then this cost implies about 25 full-time equivalents of Construction Management support. | | | |
| 17 | There is a line item for Construction Management and Daily Oversight, and separate line item for Sevenson Construction Management and Project Management Team. These items appear duplicative. Please correct as necessary. | CDM/S | Revise | Low |
| 18 | The Site Location Map depicts the areas of chlorinated VOC detections off shore of the Siltronic property but does not present similar detections of aromatic VOCs detections associated with discharge of contaminated groundwater associated with MGP operations at the GASCO site. The Site Location Map should be revised to include areas of aromatic | CDM/S | Revise | Low |
| 19 | The Site Layout Figure should depict the extent of the groundwater plume at the GASCO Site (including the adjacent Siltronic property). | CDM/S | Revise | Low |

| J | К | L | М |
|--|---------------------|----------|--------|
| Although the EE/CA guidance recommends evaluating a limited number of alternatives, the range of alternatives evaluated only includes two removal action levels – 20 mg/kg and 1.5 mg/kg BaPEq. Consideration of additional action levels should be included. The alternatives should include a single removal emphasis and a single in-place technology emphasis alternative for each RAL. Although this action is being performed as a non-time critical removal action, because the removal decision is expected to be documented in the Portland Harbor ROD, the evaluation of an expanded set of alternatives is appropriate. | CDM/S and DEQ | Evaluate | Medium |
| Alternative 5 incorporates all of the most conservative cleanup options (e.g., large dredging footprint, rigid containment [only outside Navigation Channel], removal of all substantial product, and extensive riverbank excavation and capping), and consequently represents an appropriate "bookend" alternative to Alternative 1 (No Action). However, there is no gradation in the middle remedial alternatives that incorporate some of these elements. As a result the costs and duration of Alternative 5 far exceed other alternatives. The Draft EE/CA therefore inappropriately skews the comparative evaluation of alternatives. DEO believes NW Natural should consider developing additional | | | |
| First Paragraph: The following statement needs qualification - "Any of these in-water disposal options would be appropriate for Cleanup Materials if the facilities are available for use in time for the implementation of the Gasco Sediments Cleanup Action." However, use of these CDF and CAD facilities is contingent on the material meeting the respective acceptance criteria for each facility. For example, the Terminal 4 CDF will have fairly rigid standards, especially for PCBs, which Gasco sediments may exceed. | EPA | Revise | Medium |
| First paragraph states that AOC "contemplates"AOC does not contemplate, but it spells out the performance to be expected in remediating contaminants at the site. Choose another word or revise sentence. | CDM/S | Revise | Low |
| First paragraph, 4th sentence. EPA's remedy decision for the GASCO site will not only be documented in the Portland Harbor ROD, but EPA will also select a remedy that is compatible with other site-wide cleanup activities. The text should be revised to reflect this. | CDM/S | Revise | Low |
| First paragraph under RAO3. Last sentence reads "assuming a high consumption rate of 18 grams". The word "high" should be removed. | CDM/S | Revise | Low |
| The draft FS Report states: "The reaches between RM 5 and 7 and RM 10 and 11.8, where the river is relatively narrow, contain areas of small-scale net erosion interspersed with areas of net deposition." The FS Report also states: "The model predicts that, over the long term, net erosion would be expected in the channel of RMs 5 to 7." The stretch of the Willamette River between RM 5 and 7, is an area that includes a high percentage of non-cohesive sediments relative to the rest of the Portland Harbor site. The grain size distribution pattern between RM 5.5 and 6.5 is significantly different than the patterns elsewhere within Portland Harbor with a high percentage of coarse grained, non cohesive sediments present in across much of this reach with the exception of a small band of finer grained material along the GASCO shoreline (See FS Report Figure 2.1-3). Similarly, FS Report Figure 2.1-4 demonstrates that the across much of the reach between RM 5 and 7, the river is primarily erosional. In addition the Sediment Transport Evaluation identified this reach of the river as in dynamic equilibrium. These points should be included in the discussion of sediment stability. | | Revise | Low |
| This section also includes the following statement: "Further into the navigation channel exists a relatively high-energy sediment transport zone, as evidenced by time-series bathymetry and sand grain size in this area." The lines of evidence for sediment stability presented in Figure 5.1.1.2-1 shows that much of the near shore area is category 1 (recovery is uncertain) or category 2 (recovery is somewhat less certain). Given significant concentrations of PAHs are present in surface sediments offshore of the GASCO site even though operations ceased in the 1950's demonstrates that although sediment deposition is occurring, reworking of the sediment bed continues to re-expose PAH contaminated sediments at the site. | | | |
| Second to last sentence has the word "undergoing" twice. The paragraph discussing MNR processes in the GASCO SMA will need to be revised once further direction is provided by EPA on how MNR is evaluated after review of the Portland Harbor draft FS. | CDM/S | Revise | Low |
| The last sentence refers to "following actions" but no actions are described. The Yakama believe there is some text missing . 27 | Yakama - Ridolfi | Revise | Low |
| Report title should read Engineering Evaluation/Cost Analysis GASCO Sediments Cleanup Site | CDM/S | Revise | Low |
| The implementability discussion should consider the likelihood of endangered species act consultation on the cap design and placement. As demonstrated by the capping project at the Zidell site, the use of cobbles as an armoring layer may be required. The effectiveness of cobbles at preventing erosion at the GASCO site should be discussed. | CDM/S | Evaluate | Medium |
| EE/CA Alternatives and RALs Comparison to Portland Harbor FS: The EE/CA provides alternatives 1, 2a, 2b, 3, 4 and 5. EE/CA Table 6.0-2 compares the EE/CA and FS alternatives. Even though EE/CA Table 6.0-2 provides a comparison of "technologies options", the substantial differences discussed below are not shown on the table (only mentioned in a footnote). Of course by the nature of the specific evaluations, the EE/CA is more detailed; however overall, the EE/CA alternatives are substantially different than the FS alternatives and more discussion is needed concerning these differences. | CDM/S | Develop | High |
| Reduction of Toxicity, Mobility or Volume through Treatment: The evaluations of this criteria are discussed for each alternative in Section 7 (e.g., 7.4.4 for Alternative 2a, 7.5.4 for Alternative 2b, 7.6.4 for Alternative 3, etc.). The text of these sections simply state how much active capping, how much stabilization with cement and how much dewatering is being performed. There is no discussion on how these actions affect toxicity, mobility or volume. These evaluations should be added. | CDM/S | Revise | Medium |
| Third paragraph, third sentence. The statement "the alternatives with more removal of sediment and riverbank soils results in unavoidable resuspension, release, and residuals that reduce the overall protection of human health and the environment provided by these alternatives" Although resuspension cannot be completely avoided, acknowledgement should be added that it can be mitigated if proper containment is in place. | CDM/S | Evaluate | High |
| The EE/CA states: "To support this significant bank reconfiguration, it is likely that Siltronic would need to temporarily shut down the facility, which may result in permanent loss of business and the likely termination of operations at the facility. Further, the Fab 1 building is constructed as slab on grade, such that significant structural damage resulting from undermining due to layback excavation is reasonably anticipated. Structural damage to Fab 1 will also result in permanent lost revenue and likely termination of operations at the facility. Similarly, it is anticipated that the foundation for the FAMM tank may not support the extent of layback excavation proposed in Alternative 5." However, no geotechnical or economic analysis is provided to support these conclusions. It would seem that many of the effects described here could be mitigated. Furthermore this demonstrates the need to look at additional RALs beyond the 1.5 mg/kg BaPEq used for Alternatives 4 and 5. There should also be further discussion of different technologies that do not create the same potential structural problems noted in this section. For example, removal could be truncated in the near shore area and the placement of surface cans placed within areas of shallow sediment and bank areas. | CDM/S | Evaluate | Medium |
| The statement that the no action alternative "is projected to achieve long-term surface water concentrations post-remedy that are the same as all the other alternatives" warrant further investigation. Benzo(a)pyrene surface water samples collected in the vicinity of the GASCO site exceed water quality standards. As a result, it seems reasonable to assume that remedial efforts that remove and/or isolate PAH contamination will reduce surface water concentrations following remedy completion. This is documented in the | s CDM/S | Revise | High |
| 34 modeling results, which show that surface water concentrations for the no action alternative are higher than the other alternatives following removal action implementation. | | | |

|---------|---|---------------------|----------|------------|
| ,,,,,,, | The EE/CA Report states: "empirical data on sedimentation rates, upstream sediment loads, bathymetry, and sediment core profiles reviewed in Section 5.1 indicate | CDM/S | Revise | High |
| -6 | deposition of low contaminant concentration sediments (i.e., in the range of background for PAHs) from upstream, particularly in areas with elevated COC concentrations over the long term. This supports the conclusion that a combination of active remedies and MNR would result in substantially reduced long-term sediment concentrations, as indicated by the modeling projections previously summarized." While it is true that the empirical data suggest that MNR may be effective in limited areas, the elevated levels of PAH contamination in surface sediments offshore of GASCO despite the fact that the release occurred many decades ago suggests that MNR will not be effective. In addition, areas adjacent to and within the navigation channel are even less likely to be amendable to MNR due to the presence of coarse grain sediments, anthropogenic effects such as proposed and the presence of surface sediments at higher concentrations than subsurface sediments. | | | |
| 17 | Item 6. Third sentence. The majority of GASCO sediments have not recovered naturally over the years, as this site continues to demonstrate unacceptable risks to human health and ecological receptors. | CDM/S | Revise | High |
| | | EPA | Revise | High |
| | This section does not include a discussion of worker protection that may be necessitated by higher levels of contaminants present in some dredged material. Worker safety considerations need to be reflected in this discussion on landfill selection for both Special and Hazardous Wastes. | EPA | Revise | Medium |
| 50 | The physical features presented in this section should be expanded to include areas of erosion/deposition, debris areas, areas targeted for future redevelopment, habitat areas, slope, presence of underwater utilities, presence of bedrock outcrops within the sediment bed, hot spots and areas with principle threat material (e.g., NAPL), areas with active | CDM/S | Revise | Low |
| 51 | The discussion of the nature and extent of sediment contamination should include a discussion of naphthalene. Naphthalene is the most soluble of the PAH compounds and is present at much higher levels at the GASCO site than more volatile compounds such as benzene, toluene, ethylbenzene, and xylenes (BTEX). When assessing contaminant migration, understanding the potential for naphthalene discharges is important. | CDM/S | Revise | Medium |
| 52 | It should be noted that areas of blue soil staining indicative of cyanide contamination have been detected in riverbank soils at the GASCO site. | CDM/S | Revise | Low |
| 53 | This section should include a discussion of the water quality sampling that was performed during the 2005 removal action the GASCO site. Although the 2005 removal action targeted the tar body, and thus would be expected to generate higher concentrations of dissolved constituents, the information may be use in the assessment of short term impacts during dredging activities. | CDM/S | Revise | Low |
| 54 | Somewhere in this section there should be explicit recognition that the levels of contamination offshore of the GASCO site are well above screening criteria and PRGs established at the Portland Harbor site for the purposes of the FS. A table that presents this information would be useful. | CDM/S | Revise | Low |
| 55 | EPA's November 28, 2011 comments on the October 19, 2011 Technical Briefing requested a discussion of the removal and capping of the tar body in 2005. While the 2005 removal action is discussed in Sections 2.2.4 and 4.1.1, a figure delineating the areas of remaining tar below and downriver of the FAMM dock was not provided as requested in Technical Briefing General Comment #4. | CDM/S | Develop | Low |
| | The Yakama believe that Alternative 2a seems unlikely to comply with Oregon's hot spot policy, so this alternative does not comply with ARARs (see previous comments regarding identification of hot spots of contamination). | Yakama - Ridolfi | Identify | High |
| 57 | The Project Schedule should be updated to reflect the latest understanding of the Portland Harbor Proposed Plan and ROD development schedule. | CDM/S | Revise | Low |
| 8 | The surface water RAOs focus on fluxes from contaminated sediments within the project area. This should be expanded to include groundwater fluxes. | CDM/S | Confirm | Medium |
| 9 | The performance goals focus exclusively on BaP. While this may be the driver, there are other contaminants in the area that, while they did not originate from the GASCO site (e.g., PCBs, DDx) are comingled with contamination from the GASCO site and which may require evaluation to ensure protectiveness. | CDM/S | Evaluate | High |
| 0 | Although the removal action is focused on benzo(a) pyrene, the Tribes believe the evaluation of the alternatives should address the remedial goals for all relevant contaminants. | Tribes - Stratus | Confirm | Medium |
| 51 | DEQ considers the list of COI included in Section 2.5.1.1 (see page 24) to be incomplete without "gasoline range hydrocarbons." It is unclear why this constituent was not included in the SOW and carried forward in the Draft EE/CA, as some of the highest concentrations in Portland Harbor are detected in sediments offshore of the Gasco site. Based on this information, DEQ considers gasoline range hydrocarbons to be an important site-specific COI. Furthermore, given gasoline range hydrocarbons are present above baseline ecological screening levels in offshore sediment, the Draft EE/CA should consider concentrations of this constituent to be a COPC in water and sediment for the project. | DEQ | Resolve | High |
| 2 | The EE/CA describes BaP sediment trap concentrations immediately downstream of the GASCO site in the 300 – 1,000 ug/kg range while concentrations immediately upstream are in the 20 – 50 ug/kg range. This section should note that while the downstream concentrations are below the RALs selected for evaluation in the Portland Harbor FS, they exceed the direct contact PRG of 423 ug/kg and demonstrate that the GASCO site continues to be a source of downstream PAH contamination. | CDM/S | Revise | Medium |
| 3 | Section 2.7.2 (see page 43) of the Draft EE/CA does not evaluate RG levels below background or less than 0. DEQ believes that risk-based goals that are below background should highlight the importance of background as a remedial goal. | DEQ | Revise | Low |
| 4 | Although fish tissue is used to evaluate risks associated with human fish consumption, fish consumption AWQC for benzo(a) pyrene are exceeded offshore of GASCO and elsewhere within Portland Harbor. Under CERCLA, achieving ARARs is a threshold criteria that must be met. Although there are watershed sources of carcinogenic PAHs, it is also true that GASCO represents a source of PAH surface water contamination and the EE/CA should evaluate whether reduction in surface water levels associated with the various removal alternatives is sufficient to achieve AWQC as part of the ARARs evaluation. | CDM/S | Evaluate | Medium |
| 5 | Although no archaeological deposits were observed during the removal of the "tar body," the Tribes are supportive of using an archaeologist to monitor removal actions for the Gasco sediments cleanup site. Additionally, we recommend that NW Natural consider developing an Inadvertent Discovery Plan during remedial design. | Tribes - Stratus | Comment | Low |

|----|--|---------------------|----------|--------|
| 66 | The adequacy of controls evaluation should take into account the long-term effectiveness of the sand cover to be placed following removal for Alternatives 2b, 3,4 and 5. | CDM/S | Revise | Medium |
| | First paragraph, last sentence states that EE/CA SRE is consistent with the Portland Harbor Risk Assessments. As there is still some discussion regarding the regulatory acceptance of this risk assessments, the EE/CA SRE should be based upon the final approved risk assessments. | CDM/S | Confirm | High |
| Г | End of First Paragraph: The breast-feeding exposure pathway was not used to develop remediation goals (RG) in the EE/CA per an agreement with EPA and the Yakama believe it should be included. | Yakama - Ridolfi | Confirm | Medium |
| 69 | Lines of evidence and hazard quotients greater than 1 from the BERA appear to be missing from the Draft EE/CA presentation and analysis. For example, surface water lines of evidence were inappropriately dropped through the management recommendations in the Portland Harbor draft FS and therefore were not included in the Draft EE/CA. This also applies to transition zone water. DEQ believes these additional lines of evidence need to be added back to the Draft EE/CA. | DEQ | Revise | Medium |
| | The EE/CA report states: "mass removal is not a goal supported by the sediments guidance." While it is true that mass removal alone should not be the focus, NW Natural should realize that mass removal, as it relates to long-term risk reduction, may be relevant. For example, it may be possible, through mass removal, to have greater confidence in long term effectiveness. | CDM/S | Revise | Low |
| 71 | This section describes calculating surface area weighted average concentrations (SWACs) for shoreline ½ River Miles (RM). The Yakama believe it would be preferable to average over the GASCO area of interest to reduce inclusion of areas that are not associated with the site. | Yakama - Ridolfi | | |
| 72 | The remedial alternatives include a spatially complicated mix of MNR, EMNR, capping, and removal as modified by factors such as docks, future dredging areas, etc. The Yakama believe the patterns are so complex that it would be infeasible to construct the alternatives as conceived. The GASCO site is small enough that a more plausible footprint could have been developed for each alternative. | Yakama - Ridolfi | Evaluate | Medium |
| 73 | The area should not be "parcelized" to small sub-areas that it would be impossible to implement a remedy or remedies. | CDM/S | Evaluate | Medium |
| 74 | Consistent with DEQ's September 22, 2011 letter commenting on the Revised Interim Design Report, the remedial action objectives (RAOs) for groundwater source control are to prevent migration of contaminated groundwater from the uplands to the Willamette River in a manner that minimizes DNAPL mobilization resulting from groundwater source control measures (SCMs) along the portion of the shoreline where DNAPLs occurs. Preventing contaminated groundwater from migrating to the river involves controlling and containing groundwater in the Fill water-bearing zone (WBZ) and the Alluvium WBZ. To control and contain groundwater in the Fill WBZ, DEQ accepted NW Natural's approach of using a fully-penetrating interceptor trench. The Alluvium WBZ SCM is a well-based hydraulic control and containment (HC&C) system designed to reverse hydraulic gradients from the river towards the uplands. Source control discussions presented in the Draft EE/CA (e.g., see Section 2.3.1.1) emphasize the status of the Alluvium WBZ HC&C system. However, source control will not have been achieved without preventing groundwater from both the Fill WBZ and the Alluvium WBZ from migrating to the river. NW Natural proposes to construct the interceptor trench concurrently with the riverbank cleanup included in the in-water sediment remedy. This proposal, including NW Natural's rational, was previously presented in the Revised Interim Design Report. DEQ did not approve NW Natural's proposal, determining that postponing trench construction until sometime after the in-water project is initiated will significantly delay source control of the Fill WBZ. DEQ communicated our disagreement with NW Natural's proposal and our comments on the length alignment, and sequence and schedule for construction of the interceptor trench in letters dated Sentember 22 | DEQ | Revise | High |
| 75 | NW Natural is developing a groundwater model to evaluate the performance and operation of the groundwater source control measures (SCMs). According to Section 2.3.1.1, the groundwater model and currently available data are used to predict the offshore extent of seepage control that will be achieved by the HC&C system subsequent to implementation. In addition, the groundwater model is used in conjunction with a sediment cap fate and transport model to assess the isolation cap effectiveness in Section 5.4. NW Natural indicates in Section 2.3.1.1 that the model predicts the HC&C system will reverse the groundwater gradients in the Alluvium WBZ over an area encompassing approximately 1,800 feet of shoreline and extending about 700 feet out and under the Willamette River. NW Natural further indicates that within this area: 1) seepage of groundwater from the Alluvium WBZ into the river will be prevented; and 2) concentrations of COI in sediment will decrease over time as surface water migrates from the river into the sediments. In general DEQ disagrees with these assertions and finds them to be unsupported for the following reasons: • There is no documentation provided in the Draft EE/CA regarding the model used to generate Figure 2.3.1.1-1. Although NW Natural indicates the model uses conservative assumptions, information about the model set-up, input parameters, and the site conditions to which the model is calibrated are not provided. Furthermore, the model output upon which Figure 2.3.1.1-1 is based is not included in the Draft EE/CA and DEQ is not aware of this information being previously provided to EPA and/or DEQ for review. • The uplands groundwater model referenced in the Draft EE/CA and DEQ is not aware of this information being previously provided to EPA and/or DEQ for review. • The uplands groundwater model referenced in the Draft EE/CA and DEQ is not aware of this information being previously provided to EPA and/or DEQ for review. • The uplands groundwater model referenced in the Draft EE/CA and DEQ | DEQ | Confirm | High |

| | J | К | L | М |
|----|--|---------------------|----------|--------|
| 76 | For purposes of identifying remedial alternative (Section 6), conducting detailed analyses of remedial alternatives (Section 7), and completing comparative analyses of alternatives (Section 8), the Draft EE/CA appears to presume the HC&C system will be a long-term fixture in the uplands that maintains the model-predicted hydraulic gradients from the river towards the uplands illustrated in Figure 2.3.1.1-1 for at least 100 years. However, the HC&C system is not identified in the Draft EE/CA as an element of the inwater remedy. In addition, the uplands feasibility study (FS) has not been initiated. Consequently, the HC&C system has not been subject to detailed analysis against uplands FS remedy selection factors. DEQ believes including the presence, operation, and influence of the HC&C as a baseline condition leads to overly favorable predictions regarding the long-term effectiveness of in-water remedial alternatives. Based on this information, DEQ believes it is not appropriate to rely on the HC&C to address subsurface contaminated sediment. That said, an active cap could be an effective approach to manage flux of contaminated groundwater to the river (contaminated from subsurface river sediment or otherwise). The Draft EE/CA should discuss the HC&C system in terms of being a common element of each of the in-water remedial alternatives, and fully explain how the presence or absence of the HC&C system influences predictions of the performance and effectiveness of alternatives. | DEQ | Revise | High |
| 77 | The success of any remedy at the Gasco sediments cleanup site depends in large part on the success of source control at the Gasco and Siltronic properties. The Tribes believe the predictions of flow reversal from the groundwater model should be validated before the sediment remedy is finalized. | Tribes - Stratus | Evaluate | High |
| | The EE/CA indicates that implementation of the "upland groundwater extraction system will result in a reversed groundwater gradient in the alluvial sediments" (page 61, paragraph 2). The extent of offshore groundwater capture and seepage rates are shown in Figure 2.3.1.1-1. The area of reverse flow (i.e., river to groundwater) is extensive and extends over 1,800 ft along the shoreline and 700 feet into the river. A groundwater model was used to design the groundwater extraction system (CDR, Anchor QBEA 2012b). The model extent is used to support selection of alternatives particularly related to capping in areas of substantial product (i.e., the EE/CA states that this is appropriate because flow will not be from the sediment into the river). The area of reserved flow seems very large and the modeling results should be evaluated in more detail. This detailed evaluation should present the uncertainties associated with the groundwater model and the implications associated with this uncertainty. Implications may result in a smaller | CDM/S | Evaluate | High |
| 78 | area of flow reversal than shown on Figure 2.3.1.1-1 as controlled by the vet to be completed and fully tested hydraulic containment and control system. The EE/CA states that modeling of subsurface transport due to groundwater flow "was not conducted for the GASCO Sediments Site because an underlying assumption for all EE/CA alternatives, including the no action alternative, is that source controls will be in full operation at the time of construction." Further analysis should be provided that demonstrates the degree to which groundwater source control measures will limit or minimize groundwater flow to the Willamette River such that this important transport pathway does not need to be considered. | CDM/S | Evaluate | High |
| 80 | | DEQ | Evaluate | High |
| 81 | It should be noted that effective groundwater source control is a prerequisite for an effective in-water remedy due to the potential for DNAPL migration to the Willamette River and the elevated levels of dissolved contaminants present in groundwater at the GASCO site. This is particularly true for remedies that involve the use of in place controls such as capping and in-situ treatment. Accordingly, their needs to be a presentation on the current uncertainty associated with the groundwater model and the implications of this uncertainty on the predicted success and effectiveness of the source control as well as how this uncertainty effects the in-water remedy alternatives evaluation. | CDM/S | Evaluate | High |
| 82 | The text and figure describe and show a light green hatched area where "the groundwater gradient is reversed, thereby preventing seepage of groundwater into the Willamette River." This area extends approximately 750 feet into the river. The Yakama believe it is implausible that flow reversal to this distance can be achieved. A discussion with Dana Bayuk, DEQ's site manager for the upland source control project, indicated that a preliminary model has been developed but the full-scale system will be going through a shakedown period through the end of 2012, which will be used to calibrate and verify the groundwater (MODFLOW) model. In the meantime, Mr. Bayuk doesn't think that NW Natural has supported the contention that there will be such a large capture zone for the extraction system. | Yakama - Ridolfi | Evaluate | High |
| 02 | Further discussion of the use of the impermeable geomembrane barrier to mitigate rainwater infiltration into the riverbank should be provided. Clarification should be provided on the goal of the geomembrane, the effectiveness of geomembrane at meeting the goal, and other technologies (e.g., removal) that could be utilized to achieve the same goal. Also, the cost and implementability factors associated with the use of this material should be described. | CDM/S | Evaluate | Medium |
| 84 | The last paragraph states: "The upland groundwater extraction system will result in a reversed groundwater gradient in the alluvial sediments that will cause COCs in river sediments to move toward upland extraction system where groundwater is captured and treated over time." This is a working hypothesis that has not been proven. In the Yakama's opinion, it is unlikely that an upland system can influence groundwater over such a large area. If the model indicates that it can, the model is probably poorly | Yakama - Ridolfi | Evaluate | High |
| 85 | No active remedy is proposed for the riverbank soil but it seems that most of that soil has not been sampled because of the presence of riprap, which armors against erosion. The | Yakama - Ridolfi | Confirm | Low |
| 86 | As stated in the comment regarding Section 7.2.2.2, the Yakama does not believe that the groundwater extraction system as currently proposed is an effective means of minimizing groundwater impacts. | Yakama - Ridolfi | Evaluate | High |
| ρ7 | DEQ's March 21, 2008 letter commenting on the DNAPL/Groundwater FFS (see reference below) informed NW Natural that planning, design, and implementation of uplands SCMs must take into consideration future riverbank work. Since that time DEQ has consistently maintained: • Future riverbank work should not interfere with installation and/or operation of uplands SCMs and/or DNAPL/groundwater treatment system equipment, buildings, or piping; and • Uplands SCMs should not limit NW Natural's ability to develop a complete and effective approach to addressing the riverbank. Draft EE/CA Alternatives 4 and 5 results in removal of uplands SCMs (i.e., Fill WBZ interceptor trench and Alluvium WBZ HC&C system) due to slope layback assumptions and then use this outcome to argue for elimination of these alternatives. For clarification, DEQ does not consider damage and/or destruction of uplands SCMs to be justifications for removing otherwise valid remedial alternatives from consideration in the Draft EE/CA. DEQ's comment regarding the limitations of the 3:1 slope assumption and the need for the Draft EE/CA to evaluate temporary engineering measures applies here. | DEQ | Evaluate | High |

| 96 | | Stratus | | |
| 90 | Evaluation of "substantial product": As discussed in EE/CA section 2.5.3 and many other places, RAO 1 of section 3.2 of the SOW provides a preference for removal of sediments | EPA and | Evaluate | High |
| | containing substantial amounts of product. According to EE/CA section 2.5.5 and many other places, RAO 1 of section 3.2 of the sow provides a preference for removal of sediments containing substantial amounts of product. According to EE/CA text on pg 29, visual observations from core and borings logs were placed in two categories: 1) substantial | CDM/S | Evaluate | nigii |
| | product that was solid (e.g., tar) and considered non-mobile and 2) substantial product that was in liquid form (e.g., liquid oil, saturated media, DNAPL layers) and considered | CDM/3 | | |
| | | | | |
| | potentially mobile. (Note: no material was identified in category 3). | | | |
| | | | | |
| | Except for alternative 5, most of the alternatives do not substantially address the "substantial product" identified areas in figure 2.5.3-1 with removal. Under most alternatives, | | | |
| 97 | many of the areas with substantial product are addressed by capping. This technology is evaluated as effective because groundwater modeling indicates that "upland source | | | |
| 91 | LOW OIS WILLDEVEN HOMER FORMANDE FOR DISCHARGE THE OIL OF THE THE OIL STANDENTS AS A 1 CSIM. THE TWO CASHOL AND A THE OIL STANDENTS OF THE OIL STANDENTS | Tribes - | Confirm | Medium |
| | The evaluation of the effectiveness of the engineered cap is largely based on modeling and assumptions about groundwater flow direction and velocity. The groundwater model | 1 | Connrm | Medium |
| | assumes that dissolved organic compounds moving upward through the cap will undergo biodegradation and partition onto the cap material. The Tribe believes this assumption | Stratus | | |
| | should be thoroughly evaluated with field testing before any remedy that relies on an engineered cap is implemented. | | | |
| 98 | | CDM/C | Di | N4 - 4: |
| ^~ | This paragraph states that a pilot cap was placed over the primary tar deposit removal area. NW Natural should provide a discussion of the effectiveness of this cap in | CDM/S | Revise | Medium |
| 99 | preventing contaminant migration. | ODM (C | - I | N/ 1: |
| | Overall, the evaluation of the various DNAPL LOE in Section 5.5 as well as Section 3 of Appendix I seems reasonable and it seems likely that the migration pathway of greatest | CDM/S | Evaluate | Medium |
| | consequence is DNAPL serving as an ongoing source of dissolved groundwater contamination. NW Natural should review the results of the McCormick and Baxter reactive cap | | | |
| | application with respect to groundwater flux rates, dissolved groundwater contaminant concentrations in the source area (source term) and performance monitoring results to | | | |
| | understand the degree to which active capping technologies would be effective at the GASCO site. | | <u> </u> | |
| 00 | Reactive capping technologies may be effective at controlling DNAPL transport to the Willamette River in conjunction with the upland source control action . This technology has | CDM/S | Evaluate | Medium |
| 00 | | | | |
| 00 | been successfully demonstrated at the McCormick and Baxter site and in the placement of organo-clay following the 2005 removal action at the GASCO site. Post placement | 1 | | |

|-----|--|----------|--------------------|--------------|
| | The use of a clean cover to address residuals will function as a cap. While the placement of clean material to isolate residuals is expected to be effective in the short term if placed | CDM/S | Evaluate | High |
| | immediately following the final dredge pass, evaluation of the long term effectiveness of the clean cover should be evaluated in light of the high groundwater flux at the GASCO | CDIN/5 | Evarance | 16 |
| 104 | site. | | | |
| 10 | Removal of contaminated sediments using barge mounted dredging equipment with long reach excavators equipped with narrow budgets may be effective at removing shallow | CDM/S | Evaluate | Medium |
| | sediments below and adjacent to dock structures at the GASCO site. This limited removal in conjunction with post removal cap placement may be an effective approach for | CDM/3 | Evaluate | Medium |
| | , | | | |
| 400 | addressing contamination in and around non-removable structures. To further enhance long term effectiveness, active capping materials such as reactive core mats may be | | | |
| 108 | incorporated into the cap design. NW Natural should consider the use of these methods. | CDM /C | Б 1 . | N.C. 1: |
| | Based on information presented in the EE/CA, experience at other sites, and the presence of debris and structures at the GASCO site, removal activities are expected to generate | CDM/S | Evaluate | Medium |
| | significant residuals. While the placement of a sand cover once removal operations are complete is described, evaluation of the effectiveness of this sand cover at meeting the | | | |
| | removal action objectives should be performed. In addition, based on the water quality monitoring during the 2005 removal action, significant releases are expected during | | | |
| 106 | dredging. The EE/CA should discuss the magnitude of these expected releases and describe potential control measures for controlling these releases. | | | |
| | The discussion of rigid containment should include discussion of the current dredging at the Diamond Alkalai site on the Passaic River. Due to the effectiveness of sheet pile | CDM/S | Evaluate | Medium |
| | enclosures water quality monitoring during the implementation of the dredging activity is no longer required. Methods to reduce releases at the Diamond Alkalai site include | | | |
| | application of a sealant to the sheet pile joints to reduce the interlock permeability. Scour at base of the sheet pile can be mitigated by armoring methods, such as erosion control | | | |
| 107 | mattresses or graded rock lavers, or use of sheet pile deflector walls. | | | |
| | This discussion lumps all barrier controls in one group and implies that silt curtains and rigid containment are equally ineffective (i.e., release rates observed are generally in | EPA | Revise | Medium |
| | the range of 2 to 4 percent). It seems unlikely that both barrier technologies would release the same amount of material. Further references and justification should be provided | | | |
| 108 | distinguishing between the effectiveness of each technology. | | | |
| | The EE/CA report states: Alternatives that include more dredging/removal (Alternatives 4 and 5) are projected to result in higher overall surface sediment concentrations | CDM/S | Evaluate | High |
| ĺ | [particularly for naphthalene] over substantial periods of time due to the duration of construction and the effects of dredge residuals as compared to those alternatives with | ' | | " |
| | more emphasis on in-place technologies and MNR. It should be noted that the use of sheet pile containment (with appropriate BMPs) may mitigate many of these effects by | | | |
| 109 | containing releases and perhaps allowing for work outside the dredge windows thus shortening the overall time for remediation. NW Natural Should consider evaluating the | | | |
| | The EE/CA states that because the various alternatives achieve similar contaminant levels, the "comprehensive alternatives that include greater dredging/removal volumes | CDM/S | Revise | High |
| | and/or longer construction durations (especially Alternative 5 at 10 years' duration) provide less overall protection of human health and the environment than shorter duration | 001.17.5 | The Vise | 1 |
| | alternatives that focus on in-place technologies." The evaluation of short-term impacts should be conducted as part of the short-term effectiveness. It should also be noted that | | | |
| 110 | alternatives that remove or effectively isolated a larger mass of contamination will score higher under long-term effectiveness and permanence. | | | |
| | The discussion of TZW should include discussions regarding the magnitude of toxicity reference values (TRVs) used to evaluate risks to aquatic life in the baseline ecological risk | CDM/S | Revise | Low |
| 111 | assessment (BERA) for the Portland Harbor site. The chemicals with the highest hazard quotients should be highlighted. | CDM/3 | Kevise | Low |
| - | EE/CA Interim Project Area Identification: As stated on pg 4 and Section 4 (pg 70), the EE/CA presents an "interim Project Area representing a further refinement of the lateral | CDM/S | Evaluate | High |
| | | CDM/3 | Evaluate | nign |
| | and vertical extent of SMA 9U remedial action areas". The 2009 Gasco Sediment Site Area of Interest includes the U.S. Moorings property; it is noted that SMA 9U and the EE/CA | | | |
| | interim Project Area do not include the U.S. Moorings property. The EE/CA interim Project Area includes the riverbank ("below the top of the bank as defined in the SOW"). | | | |
| | Figure 2.5.3-1 show the extent of substantial product, figure 4.4.2-1 show the comprehensive Benthic Risk Assessment Boundary, and Figure 4.4.3-1 shows the RAL contours for | | | |
| ١ | BaPEq. These three evaluations combine to form the interim Project Area shown in figure 4.4.6-1. The EPA will be evaluating the data to determine if portions of the U.S. | | | |
| 112 | Moorings area belong within the interim Proiect Area. | | <u> </u> | |
| | The U.S. Moorings RI Report describes sediment samples collected off-shore of the U.S. Moorings site as follows: "At depths between 20 – 40 inches the sediments are soft, | CDM/S | Evaluate | High |
| i | brownish olive-gray, moist silty/clays (30/70) with evidence of both thin (<1"), gray sand stringers, and black bands of PAH enriched sediments, some with mineralized PAH | | | |
| | layers." And "all the under-dock cores (except SDUD-4), Dredge Areas A and C, and at SDDB-20 the subsurface sediments contained black laminar bands of PAH enriched | | | |
| | sediment with diffuse sheen and strong PAH odor." BaP was detected in the U.S. Moorings dock area at concentrations up to 39 mg/kg. The EPA will be evaluating the data to | | | |
| 113 | determine if portions of the U.S. Moorings area belong within the interim Project Area. | | | |
| | All alternatives need to consider the removal of substantial product consistent with the SOW. In addition, the interim boundary needs to encompass all areas with substantial | CDM/S | Evaluate | High |
| 114 | product consistent with the SOW. | | | |
| | The removal action boundary should be expanded to include areas of elevated BaPEq located downstream in the vicinity of the dock areas at the U.S. Moorings site. BaP | CDM/S | Evaluate | High |
| 115 | concentrations are present at levels up to 39 mg/kg. The EPA will be evaluating the data to determine if portions of the U.S. Moorings area belong within the interim Project | | | |
| i | The EE/CA states that "sediment remediation is not expected to affect navigation to the U.S. Moorings Dock just downstream of the Gasco Sediments Site." Given the presence of | CDM/S | Evaluate | High |
| ı | elevated levels of Benzo (a) Pyrene and evidence of free product offshore of the U.S. Moorings facility, additional discussion of the U.S. Moorings Dock and berthing operations is | | | |
| 116 | required in this section. | | | |
| | The 1994 Preliminary Assessment completed by the U.S. Army Corps of Engineers for the U.S. Moorings facility included a series of sediment borings that showed evidence of | CDM/S | Evaluate | High |
| | product. In addition, the recent RI report completed by the U.S. Army Corps of Engineers also identified the presence of tar offshore of the U.S. Moorings facility. This | 1 | | 1 |
| | | 1 | | |
| 117 | information should be used to update the free product distribution figure (Figure 2.5.3-1) and should be incorporated into the revised interim action area. | | | |
| 117 | information should be used to update the free product distribution figure (Figure 2.5.3-1) and should be incorporated into the revised interim action area. The evaluation to determine the extent of "substantial product" should be expanded to include sediment cores collected off shore of the U.S. Moorings facility. The EPA will be | CDM/S | Evaluate | High |
| | | CDM/S | Evaluate | High |
